Background

Differences in ER- and HER2-expression on metastases compared to the primary tumor (PT) are a known phenomenon and may have clinical implications in respect of targeted systemic treatment approaches. The aim of this study was to evaluate both ER (+) and HER2-positive DTCs on disseminated tumor cells (DTCs) in the bone marrow (BM) of patients (pts) with early breast cancer (EBC; see table 1) and to compare these with the corresponding PT.

Methods

BM aspirates were obtained at the time of first surgery. After Ficoll enrichment for mononuclear cells two cytopsinss with 100 BM cells were evaluated for ER, HER2, and cytokeratin (CK) expressions simultaneouly by immunocytochemistry using a three fluorescence staining method with antibodies directed against human ER (secondary labeling with Cy3, red), HER2 (Coumarin-AMCA, blue) and CK (Cy5 Light488, green). The manual analysis was conducted using a computerized fluorescence microscope (Axioskop, Zeiss, Germany). Criteria for CK- and HER2-positivity were the ring-like appearance of the respective membrane stainings and for ER-expression a nuclear staining (see figure 1). Only pts with the detection of CK positive cells (CK+) and known ER- and HER2-status of the PT (n=54) were selected for this analysis.

Results

The median number of DTCs was 13 (range 1-95; total number of DTCs detected: 1092; see figure 2). 40 (74%) of the pts had at least one ER-positive (pos) DTC, 24 (44%) at least one HER2-pos DTC, 14 (26%) at least one ER+ and HER2-pos DTC, and 50 (93%) at least one ER-negative/HER2-negative (neg) DTC, while 10 (19%) pts had only ER-neg/HER2-neg DTCs.

The concordance rate between ER-status on DTCs and PT was 74%. Pts with an ER-pos PT were significantly more likely to have at least one ER-pos DTC (34 out of 42) with an ER-neg PT (6 out of 12; Chi-square test, x² = 4.66, p = 0.031; 39 (93%) of the 42 pts with ER-pos PT had at least 1 ER-neg DTC (see table 2A).

The concordance rate between HER2-status on DTCs and PT was 52%. The probability of having at least one HER2-pos DTC was not related to the HER2-status of the PT (Chi-square test, x² = 0.34, p = 0.56; 22 (46%) of the 48 pts with a HER2-neg PT had at least one HER2-pos DTC. All of the 6 pts with a HER2-pos PT had at least 1 HER2-neg DTC (see table 2B).

7 out of 10 pts with a triple-neg PT had at least one DTC pos for ER, HER2 or both. Further the heterogenity of the ER- and HER2-expression on DTCs compared to the PT for different DTC counts was evaluated. We detected all possible combinations of ER- and HER2-expression on DTCs regardless of the respective status of the PT (for details refer to table 3).

Conclusions

Our study confirms that the ER- and/or HER2-status on DTCs may differ compared to the PT. This discordance could be especially important for pts with a triple-neg PT and ER-pos or HER2-pos DTCs, since they might respond favorably to an endocrine or HER2-targeted therapy. On the other hand, the presence of neg or HER2 neg DTCs in pts with ER-pos or HER2-pos PT might explain some of the failures of adjuvant endocrine or HER2 targeted therapy.

Acknowledgement

We would like to thank all patients for participating at this study and donating their BM samples for research purposes.
