The prognostic value of CTCs at primary diagnosis has recently confirmed by the SUCCESS A study (Rack et al., JNCI 2014). Key questions on the role of adjuvant bisphosphonate treatment, including patient populations deriving benefit and optimal timing/scheduling of therapy are still controversial. Aim of this study was therefore to evaluate the predictive value of zoledronic acid treatment (for 5 years vs for 2 years) on the prevalence of CTCs at 5 years after primary diagnosis additionally to other well-known predictors.

The SUCCESS A trial is a large, randomized, open-label, 2x2 factorial design Phase III study in patients with high risk breast cancer (stage N1 or T2-T4 or grade 3 or age ≤ 35 or hormone receptor negative). Patients were first randomized to adjuvant chemotherapy treatment with 3 cycles of Epirubicin-Fluorouracil-Cyclophosphamide (FEC) followed by either 3 cycles of Docetaxel or 3 cycles of Gemcitabine-Docetaxel. In addition, patients were randomized to 2 years vs. 5 years of zoledronate treatment. CTC status before and after chemotherapy, as well as 2 and 5 years after primary diagnosis was assessed using the FDA-approved CellSearch System (Veridex, USA), and CTC positivity was defined as ≥ 1 CTC.

## Statistical Methods

The primary objective was to study the predictive value of zoledronic treatment (for 2 years vs. for 5 years) on the prevalence of CTCs at 5 years after primary diagnosis, additionally to well-known predictors. A multiple logistic regression model was fitted with CTC status at 5 years as binary outcome (0 CTCs, > 0 CTCs) and the following predictors: zoledronate treatment (categorical; 2 years vs. 5 years) age at diagnosis (continuous) BMI at diagnosis (continuous), tumour stage (ordinal; pT1, pT2, pT3, pT4), lymph node status (categorical; pN0 and pN+), ER, PR, and HER2neu (each categorical; negative vs. positive), tumor type (categorical; ductal, lobular, other) , CTC status before chemotherapy (categorical; 0 CTCs, >0 CTCs), adjuvant chemotherapy (categorical; FEC-Doc vs. FEC-DocG). The Wald test was performed for zoledronate treatment. A significant pvalue would indicate that zoledronate treatment influences the prevalence of CTCs at 5 years after primary diagnosis in addition to the considered predictors. Furthermore, the regression model was used to estimate adjusted odds ratios (ORs), especially for zoledronic treatment.

Patients with missing outcome and natients with missing CTC information at 5 years were excluded. Missing predictor values were imputed using single "best guesses" (median value of continuous predictors, the most common value of categorical or ordinal predictors) based on non-missing data across all subjects. Continuous predictors were used as natural cubic

spline functions to describe non-linear effect (Hastie and Tibshirani, 1995). The number of knots of each predictor was determined by first fitting several simple logistic regression models which differ from each other by the number of knots (from 0 to 4) and then choosing the number of knots which optimizes the Akaike information criterion (AIC).

A sensitivity analysis was performed with a reduced logistic regession model to address the problem of over- as well as underestimation of regression coefficients due to too many variables per outcome event (Harrell et al. 1984: Peduzzi et al., 1996) and related to this, the problem of overfitting. A backward stepwise variable selection procedure with AIC as stop criteria was carried out on the condition that zoledronate treatment was kept in each selection step resulting in a reduced logistic regression model with zoledronate treatment and "the most important" predictors of the full model. As above, the Wald test was performed and adjusted ORs were

The performance of the logistic regression models was measured with the area under the receiver operator curve (AUC) and the Hosmer-Lemeshow x2 test, where frequencies of predicted events were compared with frequencies of observed events. A large p-value indicates a satisfactory calibration.

Model building was evaluated by 10-fold cross-validation with 50 repetitions to measure the amount of over-fitting. For this purpose, the model building process (i.e., determination of degrees of freedom for continuous predictors, the estimation of regression coefficients, variable selections) was done on each training set resulting in a logistic regression model, which was used then to calculate the AUC on the corresponding validation data set. The average of all these AUCs was taken as evaluation measure.

All of the tests were two-sided, and a P value of < 0.05 was regarded as statistically significant. Calculations were carried out using the R system for statistical computing (version 3.0.1; R Development Core Team, Vienna, Austria, 2013)

### Patient and tumour characteristics

Data on CTC status at 5 years after primary diagnosis were available for 728 (19.4%) out of 3754 randomized patients. 65 patients (8,9%) had CTCs at five years after diagnosis and 663 (91.1%) had no CTCs, 310 patients had been randomized to 2 years of zoledronate treatment and 418 patients had been randomized to 5 years of zoledronate treatment. 93.8% of all patients had complete observations in all patients and tumour characteristics but CTCs at 2 years after diagnosis which was not considered for statistical analyses. The percentage of missing values in each predictor variable was below 0.5% except for HER2neu (1.8%) and CTC before chemo therapy (4.4%). The missing values of predictor variables were imputed

as described above, 19.2% of all patients had no information about CTCs at 2 years after diagnosis. Patient and tumour characteristics according to CTC prevalence at 5 years after diagnosis are shown in Table 1.

Zoledronic acid treatment and prevalence of CTCs at 5 years We could not show that the duration of zoledronate treatment (2 or 5 years) influenced the prevalence of CTCs at 5 years after diagnosis (p = 0.13, Wald test). The adjusted OR for 2 years vs 5 years of treatment was 0.65 (95% CI: 0.37 to 1.13). The ORs for the predictors of the full logistic regression analysis is shown in Table 2.

The reduced logistic regression model confirmed the main analysis. The adjusted OR and the p-value of the Wald test were exactly the same as above. ORs are shown in Table 3

### Model performance and evaluation

The full logistic regression model seemed to be bad calibrated whereas the calibration of the reduced model seemed to be rather good. Both models seemed to be over-fitted to a certain degree, because the cross-validated AUCs are lower than the apparent AUCs on the original data.

We could not show an influence of zoledronate treatment duration on the prevalence of CTCs five years after primary diagnosis. Other trials in this setting might provide additional information on the predictive role of CTCs in the context of
